

Morbidity and Treatment of Ailments

**NSS Fifty-second Round
July 1995 – June 1996**

**National Sample Survey Organisation
Department of Statistics
Government of India**

November 1998

PREFACE

The national Sample Survey Organisation (NSSO) in its 52nd round (July'95 – June'96) carried out a nation wide survey on social consumption to ascertain the extent of utilisation of facilities in the field of Education and Health. The survey also studied the problems of aged persons. Earlier, two comprehensive surveys on social consumption were carried out in the 35th round (July'80 – June'81) and 42nd round (July'86 – June'87).

The present report is on morbidity and mortality and health care based on the “Central Sample” data collected in the 52nd round. The report presents data on the nature of ailments and cost and sources of curative treatments received by the general population; details of patients receiving hospitalised and non-hospitalised treatments by age, sex, nature of ailments, type of institution, etc.; utilisation of various public health care facilities; private expenditure on curative medical treatment; incidence and prevalence of various chronic and acute ailments.

The field work of the survey was conducted by the Field Operations Divisions. Data scrutiny and tabulation were handled by Data Processing Division. The Survey Design & Research Division was responsible for the designing of the survey and preparation of the report.

I am grateful to the members of the Governing Council and members of the Working Groups for their valuable guidance at various stages of the survey work. I also wish to thank the heads of the various divisions of NSSO and their colleagues for their efforts in conducting the survey and bringing out this report. It is hoped that this report would serve as a reference document to the users of NSS data.

Your Comments and suggestions are most welcome.

November 1998

*Dr. N. S. SASTRY
Director General & Chief Executive
Officer

List of Appendix Tables

<i>Chapter I</i> Introduction	i
<i>Chapter II</i> Concepts and Definitions	1
<i>Chapter III</i> Sample Design and Estimation Procedure	4
<i>Chapter IV</i> Summary of Findings	11
<i>Appendix</i> Detailed Statewise Statistical Tables	A1

HIGHLIGHTS

Rural Urban

Proportion of Ailing Persons by Residence Status & Sex

**Number (per 1000) of persons reporting ailment
(PAP) during a period of 15 days**

Male	54	51
Female	57	58
person	55	54

Interstate Variation in Level of Morbidity

**States with relatively high PAP during a period of 15
days**

Kerala	118	88
Assam	80	86
Punjab	76	85

**States with relatively low PAP during a period of 15
days**

Rajasthan	28	33
Bihar	36	41
Madhya Pradesh	41	38
Gujarat	46	36

Treatment of Ailments

Percentage of Ailing Persons Treated During 15 Days

Male	84	91
Female	82	90
Person	83	91

Reason for No Treatment

**Percentage distribution of untreated ailments by
reason for no treatment**

no medical facility	9	1
lack of faith	4	5
long waiting	1	1
financial problem	24	21
ailment not serious	52	60
others	10	12
all	100	100

Sources of Non-hospitalised Treatment

**Percentage distribution of non-hospitalised
treatments by source of treatment**

Public hospital	11	15
P.H.C./C.H.C.	6	1
Public dispn.	2	2
ESI doctor, etc.	0	1
all govt. sources	19	20
Private hospital	12	16
Nursing home	3	2
Charitable inst.	0	1
Private doctor	55	55
Others	10	7
all non-govt. sources	81	80
Total	100	100

HIGHLIGHTS (Continued)

	Rural	Urban
Hospitalised Treatment		
Number (per 1000) of persons hospitalised any time during a period of 365 days		
Male	14	20
Female	13	20
Person	13	20
Percentage distribution of hospitalised treatments by type of hospital		
Public hospital	399	418
PHC/CHC	48	9
Public Dispensary	5	4
all govt. sources	438	431
Private hospital	419	410
Nursing home	80	111
Charitable institution	40	42
others	8	6
all non-govt. sources	562	569
all hospitals	1000	1000
	Rural	Urban
Cost of Treatment		
Total expenditure (Rs.) for non-hospitalised treatment per ailment during a period of 15 days		
Male	151	187
Female	137	164
Person	144	175
Total expenditure (Rs.) per hospitalisation during a period of 365 days	Rural	Urban
Male	3,778	4,185
Female	2,510	3,625
Person	3,202	3,921

CHAPTER I

Introduction

1.1 The National Sample Survey Organisation (NSSO)

1.1.1 The NSSO was set up in 1950 as a permanent survey organisation to collect data on various facets of the Indian economy through nationwide sample surveys in order to assist in socio-economic planning and policy-making. The NSSO covers different subjects, such as employment and unemployment, consumer expenditure, land holdings, livestock enterprises, debt and investment, social consumption, morbidity and disability, etc., through household surveys. The NSS is a continuous survey in the sense that it is carried out in the form of successive "rounds", each round usually of one-year duration covering several topics of current interest in a specific survey period. The survey programme conforms to a cycle over a period of ten years, some topics being repeated once in ten years and some being repeated once in five years. Other subjects of special importance are also accommodated in the intervening years or covered along with regular repeated surveys. At present, an NSS round at the all-India level surveys about 12,000 to 14,000 villages and urban blocks in the Central sample (covered by the Central agency, the NSSO) and an independent sample of about 14,000 to 16,000 villages and urban blocks in the State sample (covered by the Governments of various States and Union Territories).

1.2 The Present Report

1.2.1 The present report is based on the enquiry on morbidity and health care conducted in the 52nd round (July 1995 - June 1996) of the NSSO. The enquiry covered the curative aspects of the general health care system in India and also the mother and child health (MCH) care programmes. This report presents the survey results relating to utilisation of the

curative health care system and a morbidity profile of the population. Estimates of expenditure incurred for treatment of ailments are also included. In addition, results on hospitalised treatment of ailments are also provided separately in the report. Utilisation of the MCH programmes is covered in a separate report.

1.2.2 *Layout of the report:* The report contains four chapters, including the present one, and an appendix. Chapter II provides a brief discussion of the definitions and concepts used for the enquiry. Chapter III gives a fairly detailed description of the sample design and the estimation procedure used for the survey. Chapter IV discusses the summary results of the survey and attempts to provide a perspective for proper interpretation of the results. The Appendix, which, in fact, forms the main body of the report, presents the detailed survey results on morbidity and treatment of ailments in the form of tables.

1.2.3 The estimates presented in the report are based on the pooled data of the two *sub-samples* of only the *Central sample*. (See the section "Method of Data Collection" for discussion on *sub-sample* and *Central sample*). The survey results presented in the report are mostly in the form of ratios. The basic aggregate estimates of population and number of households, given in the detailed tables of the Appendix, generally as marginal column totals, may be used for working out rates and ratios for domains not presented in the report.

1.2.4 Generally, NSS estimates of population tend to be low, while estimates of rates and ratios are more robust. In the present round, an equal probability sampling scheme for villages was used, giving all villages in a stratum equal probability of inclusion in the sample. The usual NSS practice is to select villages with

probability proportional to (last) Census population, smaller villages being deliberately under-represented in number (though not under-represented in terms of population content) in the sample. The rural population estimates obtained from the survey are found to diverge more from the respective Census-based population projections than usual. These findings, of course, need further analysis.

1.3 Fifty-second Round

1.3.1 The four main topics covered in the 52nd round are:

- (i) Utilisation of maternity and child health care services
- (ii) Morbidity and utilisation of medical services
- (iii) Problems of aged persons
- (iv) Participation in education

In addition, the topics of household consumer expenditure and employment-unemployment were covered as is usually done in every round.

1.3.2 The object of the present survey was essentially to study the benefits derived by various sections of the population from investments and outlays made by the Government, as well as by the private sector in the fields of health and education.

1.3.3 The two main schedules used in the 52nd round, apart from Schedule 1.0 on consumer expenditure, were: Schedule 25.0 on maternity and child health care, morbidity and utilisation of medical services, and problems of the aged persons; and Schedule 25.2 on participation in education.

1.3.4 The entire area of the country, was covered with the exception of some interior areas of Nagaland and Andaman & Nicobar Islands and the Ladakh, Kargil and Dodha

districts of Jammu & Kashmir.

1.4 Method of Data Collection

1.4.1 The present report is based on the information on morbidity and treatment of ailments collected in Schedule 25.0. The data were collected from a sample of households by the interview method. A set of probing questions was put to as many individual members of a selected household as possible to ascertain whether they had suffered from any ailment during the reference period and whether they had taken any medical treatment for it. As far as possible, all the adult male members of each sample household were interviewed personally. For the female members, interviews were conducted through intermediaries in some cases. For the children, particularly the young, attempts were made to get the required information from their mothers.

1.4.2 *Reference period:* The enquiry on morbidity was conducted with a reference period of 15 days. All spells of ailment suffered by each member of the sample household during the 15 days preceding the date of enquiry, whether or not the patient was hospitalised for treatment, were covered in the survey. For hospitalised treatment, however, information was collected for every event of hospitalisation of a member, whether living or deceased at the time of survey, during the 365 days preceding the date of enquiry.

1.4.3 *Sample design:* The sample design adopted for the survey was essentially a two-stage stratified design, with census villages and urban blocks as the first-stage units(FSUs) for the rural and urban areas respectively, and households as the second-stage units(SSUs). The survey period, July 1995 - June 1996, was split up into four sub-rounds of three months each. The rural

and urban samples of FSUs were drawn independently in the form of two sub-samples and equal numbers of FSUs of each sub-sample were allocated for the four sub-rounds. (For a detailed discussion on sample design, see Chapter III.)

1.4.4 Sample size -- first-stage units: In all, 16,480 villages were planned to be surveyed in this round. Of these, 7888 were allocated to the Central sample -- the part surveyed mainly by the NSSO field staff -- and the rest to the State sample -- the part surveyed by the State agencies. In the urban sector, the allocations for the Central and State samples were, respectively, 5112 and 6320 blocks. This report is based on the estimates obtained from the Central sample alone. The number of villages and that of urban blocks actually surveyed as the Central sample were 7,663 and 4,991, respectively.

1.4.5 Sample size -- second-stage units: For Schedule 25.0, 10 households were planned to be surveyed in each selected FSU. In the Central sample, the actual numbers of households surveyed in the rural and urban areas were 71,284 and 49,658, respectively.

1.5 Surveys on Morbidity and Social Consumption of NSSO

1.5.1 The survey on morbidity was conducted for the first time in the seventh round (Oct. 1953 - March 1954). This survey and the morbidity surveys conducted in the three subsequent rounds (the eleventh to the thirteenth, 1956-58) were all exploratory in nature. The aim of these surveys was to evolve an appropriate data collection method for studying morbidity profile in India. These surveys were followed up by a pilot survey in the seventeenth round (Sept. 1961 - July 1962) to examine alternative approaches of

morbidity reporting. With the aid of the findings of these exploratory surveys, a full-scale survey on morbidity was conducted in the twenty-eighth round (Oct. 1973 - June 1974). Since then, the NSSO has not undertaken any separate morbidity survey. Morbidity data are now collected as a part of the decennial surveys on social consumption.

1.2.1 The NSSO carried out the first all-India Survey on Social Consumption in its 35th round (July 1980 - June 1981). The items covered were the public distribution system, health services including mass immunisation and family welfare programmes, and educational services. The results of the survey could not be brought out owing to some unavoidable reasons. The second survey on Social Consumption was carried out in the 42nd round (July 1986 - June 1987) with some modifications in the coverage of subjects. Topics like Problems of Aged Persons were included in this round. The third Survey on Social Consumption, was carried out in the 52nd round (July 1995 - June 1996). Two topics, viz. utilisation of the public distribution system and utilisation of family planning services, were dropped, as these were covered in the NSS 50th round and in a nationwide survey by the Ministry of Health and Family Welfare, respectively.

Chapter II

Concepts and Definitions

2.1.1 The concepts and definitions of the terms used in this report are briefly discussed in this chapter. For better morbidity reporting, some probing questions were put to the informants during data collection. Such special attempts to elicit information on morbidity and treatment of ailments are also indicated in this chapter.

2.2.1 *Household*: A group of persons normally living together and taking food from a common kitchen constitutes a household. The word “normally” means that temporary visitors are excluded but temporary stay-aways are included. Thus a son or daughter residing in a hostel for studies is excluded from the household of his/her parents, but a resident employee or resident domestic servant or paying guest (but not just a tenant in the house) is included in the employer/host's household. “Living together” is usually given more importance than “sharing food from a common kitchen” in drawing the boundaries of a household in case the two criteria are in conflict; however, in the special case of a person taking food with his family but sleeping elsewhere (say, in a shop or a different house) due to space shortage, the household formed by such a person's family members is taken to include the person also. Each inmate of a mess, hotel, boarding lodging house, hostel, etc., is considered as a single-member household but a family living in a hotel is considered to be one household only; the same applies to residential staff of such establishments.

2.3.1 *Ailment -- illness or injury*: Ailment, i.e. illness or injury, is defined to be any deviation from the State of physical or mental well-being. Cases of visual, hearing, speech and locomotor disabilities are also treated as ailment. Injury covers all types of damages like cuts, wounds, haemorrhages, fractures and burns caused by an accident,

including bites to any part of the body.

2.3.2 Cases of sterilisation, insertion of IUD, getting MTP, etc., under family planning programme, pregnancy and child birth are not treated as ailment. But a spontaneous abortion, is treated as a deviation from the State of normal health and thus considered to be illness.

2.3.3 For ascertaining whether an individual had suffered from any ailment during the reference period and whether she/he had received any medical treatment on that account, the following set of probing questions was put to the informant:

- During the reference period, did the member feel anything wrong relating to skin, head, eyes, ears, nose, throat, arms, hands, chest, heart, stomach, liver, kidney, legs, feet or any other organ of the body?
- Does the member suffer from any disease of a chronic nature relating to stomach, lungs, nervous system, circulation system, bones and joints, eye, ear, mouth or any other organ of the body?
- Does the member have any kind of hearing, visual, speech or locomotor disability?
- Did the member take, during the reference period, any medicine or medical advice for his/her own ailment or injury?

2.4.1 *Spell of ailment*: A continuous period of sickness owing to a specific ailment is treated as a spell of ailment. A spell is generally identified with a specific cause of ailment. If a person was reported to have suffered from two or more causes of ailment during the reference period, it was recorded as two different cases of ailment.

2.5.1 *Hospitalisation*: A person is regarded as having been hospitalised if he/she has availed of medical services as an indoor

patient in any medical institution. However, hospitalisation of female members for child-birth was not considered to be hospitalisation for the survey.

2.6.1 Medical treatment: A person is considered to have received medical treatment if he/she consults a doctor anywhere (in OPD of a hospital, community health centre, private residence, etc.) and obtains medical advice for the ailment. Self-doctoring or acting on the advice of a non-medical person is not treated as medical treatment.

2.7.1 Expenditure for medical treatment: Total expenditure incurred for medical treatment received during the reference period (15 days for non-hospitalised treatment and 365 days for hospitalised treatment) includes expenditure on items like

- bed charges (with charges for food included in it)
- medicines (including drips)
- materials for bandage, plaster, etc.
- fees for the services of medical and para-medical personnel
- charges - for diagnostic tests
- operations and therapies
- charges of ambulance
- costs of oxygen, blood, etc.

All other types of expenditure incurred for treatment, such as lodging charges of escort, attendant charges, cost of transport other than ambulance, and cost of personal medical appliances, are excluded from medical expenditure.

2.8.1 Fractile group by monthly per capita consumption expenditure: Monthly per capita consumption expenditure(mpce) based on data collected for broad heads of consumption expenditure was computed for each sample household. Using the mpce

figures of the households, the population was classified into seven fractile groups separately for rural and urban areas. The population percentiles on which the fractile groups used for the tables in the Appendix are based are given in *Table 2.1* below.

Table 2.1
Population percentiles (Rs. 0.00) of distribution of mpce for rural and urban areas of India

percentiles	rural	urban
10th	178.66	243.28
20th	208.56	296.60
40th	258.75	387.57
60th	313.00	497.33
80th	398.40	673.60
90th	480.00	875.60

It may be noted that the percentiles given in the table differ from those given in NSS Report No. 440: *Household Consumer Expenditure and Employment Situation in India, 1995-96*, which is also based on data collected in the present survey. This is because the estimates given in Report No. 440 are based on the data collected through the elaborate schedule of enquiry generally used in the NSS for collecting consumption data, while the estimates in Table 2.1 are based on consumption data collected through a much smaller set of questions.

Chapter III

Sample Design and Estimation Procedure

3.1 Sample Design

3.1.0 *General:* A stratified two-stage sample design was adopted in this round. The first-stage units were the census villages for the rural areas (panchayat wards in case of Kerala) and the NSSO Urban Frame Survey(UFS) blocks for the urban areas. The second-stage units were the households in both cases.

3.1.1 *Sampling Frame for First Stage Units (FSUs):* The lists of census villages of the 1991 census (1981 census list for Jammu & Kashmir) constituted the sampling frame for the rural areas. For Kerala, however, the list of panchayat wards was used as the sampling frame for the selection of first-stage units in the rural areas. For Nagaland, the villages located within 5 kms. of a bus route constituted the sampling frame, whereas for Andaman & Nicobar Islands, the list of 'accessible' villages formed the sampling frame. For the urban areas, the list of NSSO Urban Frame Survey(UFS) blocks was used as the sampling frame.

3.1.2 *Stratification:* For the socio-economic surveys of the NSSO, each State or Union Territory (U.T.) is divided into one or more agro-climatic regions by grouping contiguous districts which are similar with respect to population density and crop pattern. In Gujarat, however, some districts are subdivided for the purpose of region formation on the basis of location of dry areas and the distribution of tribal population in the State. In all, there are 78 regions covering the entire geographical area of the country.

3.1.3 *Stratification for rural areas:* In the rural areas, each district within a region was treated as a separate stratum. However, if the 1991 census population of the district was found to be greater than or equal to 2 million (1.8 million population as per 1981 census for Jammu & Kashmir), the district was split into two or more strata, by grouping contiguous tehsils to form strata. In Gujarat, in the case of districts extending over more than one NSS region, the part of a district falling within each NSS region formed a separate stratum.

3.1.4 *Stratification for urban areas:* In the urban areas, strata were formed, within each NSS region, by grouping towns on the basis of the population of towns. The urban strata were formed as shown in *Table 3.1.*

Table 3.1
Composition of urban strata in an NSS region

Stratum No.	Population size class (as per 1991 Population Census) of towns
1	all towns with population less than 50,000
2	all towns with population 50,000 - 1,99,999
3	all towns with population 200,000 - 9,99,999
4, 5, ...	each city with population 10,00,000 or above

* in 24 clusters around selected nucleus villages.

3.1.5 Allocation of first-stage units (FSUs): A sample of 13,000 FSUs (rural & urban combined) was selected as the 'Central sample' at the all-India level. The sample size of FSUs (rural & urban combined) for the Central sample for a State/U.T. was allocated to its rural and urban areas considering the relative sizes of the rural and urban population with double weightage to the urban areas. The State-level rural sample size was allocated to the rural strata in proportion to their rural population figures as per the census. Similarly, urban sample size of the State/U.T. was allocated to the urban strata in proportion to urban population figures as per the census. All the stratum-level allocations were adjusted to multiples of 8 as far as possible (otherwise to multiples of 4) in order to allocate them equally in each sub-sample X sub-round combination (2 sub-samples X 4 sub-rounds). Allocation of first-stage units for rural and urban areas of each State is given in *columns 2 and 3 of Table 3.2*.

3.1.6 Selection of First Stage Units: The sample FSUs in the rural areas were selected circular systematically with *equal* probability. In the Union Territory of Daman & Diu, the district Diu consists of only two villages. These two were selected for the survey in both the Central and the State sample. Sample blocks in the urban areas were also selected circular systematically with equal probability. Sample FSUs of both rural and urban areas were selected in the form of two independent sub-samples. The only departure from the general procedure of selection of FSUs was made for the rural areas of Arunachal Pradesh, for which the procedure of cluster sampling was followed. The nucleus villages were selected circular systematically with equal probability, in the form of two independent

sub-samples. A cluster, generally of 4 to 6 villages, was formed around each nucleus village. The State/U.T. -wise numbers of FSUs actually surveyed are given in *columns 4 and 5 of Table 3.2*.

3.1.7 Selection of Hamlet-Groups/ Sub-Blocks (for 'large' FSUs only): A large FSU was divided into a suitable number of hamlet-groups/ sub-blocks having approximately equal population content. Two hamlet-groups were selected from each large FSU in the rural areas and only one sub-block was selected from each large FSU of the urban areas.

3.1.8 Selection of Households (Second-Stage Units): In each of the selected FSUs, three different enquiries, viz. "Survey on Health Care", "Survey on Participation in Education" and "Survey on Consumer Expenditure", were conducted on three independent samples of households. For the present enquiry, i.e. the survey on "Health Care", a sample of 10 households was selected for the detailed enquiry. However, before selection, the listed households were first grouped into two second-stage strata. The composition of the second-stage strata and the number of sample households selected from each of them are shown in *Table 3.3*. The number of households surveyed in each State/U.T. is given in *columns 6 and 7 of Table 3.2*.

Table 3.3: Second-stage stratum composition and number of households selected

No.	second-stage stratum Composition	no. of households selected
1	households with at least one child of less than one year	2
2	of the remaining households, those reporting any case of hospitalisation	2
3	remaining households	6

3.2 Estimation Procedure

3.2.0 The notation used for describing the procedure of estimation is given below:

- s: subscript for stratum
- i: subscript for sample village/block
- j: subscript for second-stage stratum of households within a sample village/block
- k: subscript for sample household
- b: subscript for sub-sample

N_s = total number of villages/blocks in the frame of the s^{th} stratum

n_s = number of villages/blocks surveyed (including uninhabited and 'zero cases' but excluding casualty and other 'not received cases') in the s^{th} stratum , for any particular schedule type

D = total number of hamlet-groups/sub-blocks formed in the sample village/block

($D = 1, 4, 5, 6, \dots$ for rural samples

and $D=1, 2, 3, 4, \dots$ for urban samples)

The symbol D' used for the rural areas is described as :

$D' = D$ for $D=1$ and $D' = D/2$ if $D \geq 4$

H = total number of households listed in the FSU

h = number of households surveyed and used for tabulation

x, y = the two characters x & y under study

\bar{X}, \bar{Y} = estimates of population totals of the characters x, y

3.2.1 **Estimates of aggregates** : The formulae for obtaining \bar{Y}_s , the estimate of aggregate of any character y for the s^{th} stratum, are given below:

Rural:

$$\bar{Y}_s = \frac{N_s}{n_s} \sum_{i=1}^{n_s} D'_{si} \sum_j \frac{H_{sij}}{h_{sij}} \sum_{k=1}^{h_{sij}} y_{sijk} \quad \dots \dots \dots \quad (1)$$

Urban:

$$\bar{Y}_s = \frac{N_s}{n_s} \sum_{i=1}^{n_s} D_{si} \sum_j \frac{H_{sij}}{h_{sij}} \sum_{k=1}^{h_{sij}} y_{sijk} \quad \dots \dots \dots \quad (2)$$

These formulae were used to obtain sub-sample-wise estimates first and then pooled estimates were obtained as the simple averages of the sub-sample-wise estimates.

3.2.2 *Sub-sample estimates*: Sub-sample estimates were computed on the basis of villages and blocks surveyed in the sub-sample concerned. Thus n_s in the above formula denotes the number of surveyed villages/blocks in the sub-sample concerned of the s^{th} stratum.

3.2.3 *Combined estimate*: The combined estimate based on the whole sample was computed as the simple average of the sub-sample estimates. Thus, if \bar{Y}_{sb} and \bar{Y}_{s2} be the sub-sample estimates of s^{th} stratum total, the combined estimate was obtained as

$$\bar{Y}_s = \frac{1}{2} \sum_{b=1}^2 \bar{Y}_{sb} \quad \dots \dots \dots \quad (3)$$

3.2.4 *Estimate of aggregates at State/U.T./region level*: Let \bar{Y}_b be the estimate of aggregate at State/u.t/region level from b^{th} sub-sample and \bar{Y}_c the combined estimate of aggregate at State/u.t/region level based on the whole sample, then

$$\vec{Y}_b = \sum_s \vec{Y}_{sb} \quad \dots \dots \dots \quad (4)$$

$$\text{and } \bar{Y}_c = \frac{1}{2} \left(\sum_s \bar{Y}_{s1} + \sum_s \bar{Y}_{s2} \right) \quad \dots\dots(5)$$

3.2.5 Estimate of a ratio: If X be the population total of the variable x for the State /U.T./ region, its estimates \bar{X}_b , or \bar{X}_c are obtained in exactly the same manner as above after replacing y by x . Then

the estimates of the ratio $R = \frac{Y}{X}$ are obtained as

$$R^b = \frac{Y_b}{X_b} ,$$

based on sub-sample b ,

$$\text{and } \bar{R}_c = \frac{\bar{Y}_c}{\bar{X}_c} ,$$

based on the whole sample.

CHAPTER IV

Summary of Findings

4.1 General

4.1.1 The present enquiry on morbidity and utilisation of medical services was carried out as a part of the survey on social consumption in the 52nd round of the NSSO. The objective of the survey was essentially to study the utilisation of public and private health services by various sections of the population. This survey assumes special significance as the first comprehensive study on the general health care system in India which is capable of reflecting the outcomes of the National Health Policy formulated and enacted in 1983. The last survey on the subject was conducted in the 42nd round of the NSSO in 1986-87 -- too early to register the effects of the policy.

4.1.2 This report deals with the curative aspects of the general health care system in India and presents the survey results relating to utilisation of the health services and a morbidity profile of the population. All the survey results presented in this chapter, unless otherwise specified, are based on the detailed results given in the tables of the Appendix.

4.1.3 The major findings of the enquiry on morbidity and utilisation of medical services are summarised in this chapter. The first part deals with morbidity rates and the factors underlying the observed differentials. The next part draws attention to the complex nature of the relationship between self-perceived morbidity reporting and some objective standard of morbidity on the basis of analytical and empirical evidence. The

utilisation of public and private health care services for treatment of ailments is then examined in some detail. The chapter ends with a discussion of the survey results on expenditure incurred for hospitalised and non-hospitalised treatment, and the roles played by the public and private sectors in providing health services to the people.

4.2 Morbidity Rates

Table 4.1

Number (per 1000) of persons reporting ailment (PAP) during the 15 days preceding the date of survey

area	ailment	male	female	all
Rural	acute	41	44	42
	chronic	13	14	13
	any	54	57	55
Urban	acute	39	43	41
	chronic	13	15	14
	any	51	58	54

Note: The short-duration (less than 30 days) ailments are referred to as *acute* ailments, and long-duration (30 days or more) ones as *chronic* ailments.

4.2.1 *Level of Morbidity:* Table 4.1 gives the survey estimates on prevalence of morbidity, measured as the number of persons reporting ailment during 15 days per 1000 persons. It shows little difference in the rate between rural and urban areas. The rate differed little between the male and female population of rural India, though a perceptible gender difference seems to have existed in urban areas. It may be noted once again that the normal pregnancy and childbirth related events were not treated as sickness in the survey; only the

complications of pregnancy and childbirth were considered as ailments.

4.2.2 The morbidity rate given in *Table 4.1* is different from the *prevalence rate*, as recommended by the W.H.O. Expert Committee on Health Statistics. Generally, *prevalence rate* is defined as the ratio between the number of spells of ailment suffered at any time during the reference period and the population exposed to the risk. It measures the frequency of illnesses prevailing during the reference period, whereas the table gives the estimated proportion of persons reporting ailment suffered at any time during the reference period. Strictly speaking, the estimates given in the table are, therefore, not *prevalence rates*.

4.2.3 As the estimates are based on self-reported morbidity data, rather than on medical examination, the information on number spells of different ailments suffered during the reference period is not likely to reflect the objective illness-status of the patients, particularly the number of diseases a patient is afflicted with. Thus, only the estimated proportion (number per 1000) of **ailing persons** (PAP) is used as a measure of morbidity prevalence in this report. The survey estimates of *prevalence rates*, given in *Table 4.3*, are meant for comparison with the estimates of the earlier rounds.

4.2.4 *Acute and chronic ailment:* It is seen that the gender-specific PAPs for acute ailments were about three times of those for chronic ailments, both in rural and urban areas of the country. The nature of ailment, i.e. acute or chronic, was determined on the basis of the type of ailment (i.e. the disease reported by the patient). The type of ailment, as reported by the respondent, was recorded for every spell of ailment in form of codes, so structured as to make the distinction between short-duration (less than 30 days)

and long-duration (30 days or more) ailments possible. In this report, the 'short-duration' ailments are referred to as acute ailments and the 'long-duration' ailments as the chronic ailments. The lists of distinct 'short-duration' and 'long-duration' ailments used for data collection are given in the next page.

4.2.5 *Age-specific morbidity prevalence:* *Figure 4.1* shows the age-specific morbidity prevalence, measured as PAP, separately for acute and chronic ailments by rural-urban residence. It is seen that, both for rural and urban areas, age patterns of PAP for acute ailments differ markedly from those for chronic ailments. However, the patterns do not differ much by rural-urban residence. For both rural and urban areas, age-specific PAPs for acute ailments show a distinct U-shaped pattern, while those for chronic ailments a positively-slopped pattern. Both for acute and chronic ailments, morbidity prevalence is found to be much higher among those aged 60 years or more than the other age-groups.

4.2.6 *Level of Morbidity -- rural-urban differential:* *Table 4.2* gives the gender-specific morbidity rates like PAP and PPC by rural-urban residence. The PPC is measured as the proportion (number per 1000) of persons reporting commencement of any ailment during the reference period of 15 days preceding the date of survey. It may be noted that the PPC is different from incidence rate, as recommended by the W.H.O. Expert Commission on Health Statistics. While the incidence rate measures the frequency of illnesses commencing during a reference period, the PPC gives the estimated proportion of persons reporting commencement of any ailment.

List of distinct short-duration and long-duration ailments used for data collection

short-duration ailments:

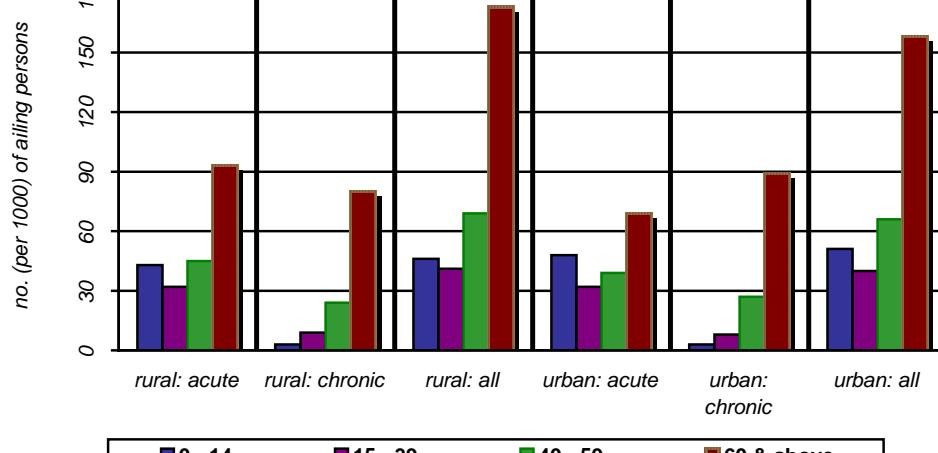

1. Diarrhoea & gastroenteritis dysentery (including cholera)
2. tetanus
3. diphtheria
4. whooping cough
5. meningitis & viral encephalitis
6. fevers of short duration
7. chicken pox
8. measles/German measles
9. mumps

10. diseases of eye
11. acute disease of ear
12. heart failure
13. cerebral stroke
14. cough and acute bronchitis
15. acute respiratory infection (including pneumonia)
16. diseases of mouth, teeth & gum
17. injury due to accident and violence
18. other diagnosed ailment (up to 30 days)
19. undiagnosed ailment (up to 30 days)

long-duration ailments:

- | | | |
|----------------------------------|-----------------------------------|---|
| 1. Chronic amebiasis | 13. beri beri | 26. piles |
| 2. pulmonary tuberculosis | 14. ricket | 27. speech disability |
| 3. sexually transmitted diseases | 15. other malnutrition diseases | 28. diseases of mouth, teeth & gum |
| 4. leprosy | 16. mental & behavioral disorders | 29. gastritis hyper-acidity /gastric /peptic / duodenal ulcer |
| 5. jaundice | 17. epilepsy | 30. diseases of kidney/urinary system |
| 6. guinea worm | 18. other diseases of nerves | 31. prostate disorders |
| 7. filaria (elephantiasis) | 19. cataract | 32. hydrocele |
| 8. cancer | 20. other visual disabilities | 33. pain in joints |
| 9. other tumors | 21. other diseases of the eye | 34. other disorders of bones and joints |
| 10. (general debility) anaemia | 22. hearing disability | 35. locomotor disability |
| 11. goitre & thyroid disorders | 23. other diseases of the ear | 36. other congenital deformities (excluding disability) |
| 12. diabetes | 24. diseases of heart | 37. other diagnosed diseases (more than 30 days) |
| | 25. high/low blood pressure | 38. undiagnosed ailment (more than 30 days) |
-

Figure 4.1
Age-specific morbidity prevalence (PAP)

4.2.7 Like the PAPs, the PPCs do not reflect any perceptible rural-urban differential. The observed equal levels of morbidity reportage in rural and urban areas is, apparently, contrary to the poorer health conditions in rural areas reflected by the health indicators like infant mortality rate and mortality rate at other ages, expectation of life at birth, etc.. A likely factor obscuring the rural-urban differential may be the higher level of health consciousness in urban areas, leading to a higher illness reporting by urban households compared to the rural households with the same level of morbidity.

4.2.8 *Level of Morbidity -- inter-state comparison:* The estimated number (per 1000) of ailing persons (PAP) and persons reporting commencement (PPC) of any ailment for the 15 major states are presented in *Table 4.3* for inter-state comparison of level of morbidity. The observed differences in PAPs or PPCs, it may be noted, do not reveal the difference in the actual health status, rather they confirm the widely held view that self-perceived morbidity reporting is highly influenced by the general health consciousness prevailing among a population.

4.2.9 *Table 4.3* reveals large inter-state variations in PAP as well as PPC in both rural and urban areas. The level of morbidity for rural areas, measured in terms of PAP, varied from 28 in Rajasthan to 118 in Kerala. The variation in PPC ranged from 15 in Rajasthan to 60 in Kerala. Comparatively, the inter-state variation in morbidity reporting of urban areas was less pronounced, with PAP ranging from 33 in Rajasthan to 88 in Kerala and PPC ranging

Table 4.2

Number (per 1000) of persons reporting ailment (PAP) and number (per 1000) of persons reporting commencement of any ailment (PPC) during last 15 days

		India	
gender	area	PAP	PPC
male	rural	54	30
	urban	51	30
female	rural	57	32
	urban	58	31
person	rural	55	31
	urban	54	30

Note that the estimate of PPC given in the table differs from the estimates in Tables 9.1 & 9.2 of the Appendix, since the former relates to all ailments -- both acute and chronic -- while the latter only to acute ailments.

from 19 in Rajasthan to 43 in Kerala. It is, however, seen that the states with relatively high morbidity reporting in rural areas, also reported high morbidity in urban areas. In fact, for both rural and urban areas, the states of Kerala, Assam and Punjab were at one extreme reporting high levels of morbidity and Rajasthan, Bihar, Madhya Pradesh and Gujarat were at the other with low levels of morbidity reporting.

Figure 4.2
Rural and urban PAPs in 15 major states

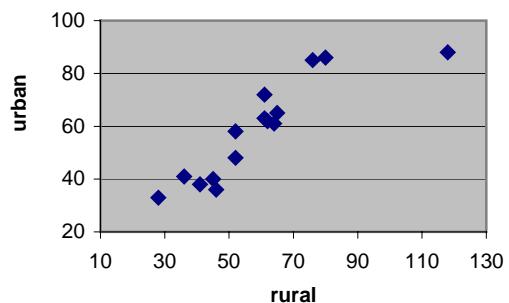

Table 4.3

Number (per 1000) of persons reporting ailment (PAP) and number reporting commencement of any ailment (PPC) during last 15 days along with mortality rate (IMR)

state / u.t.	Rural			Urban		
	PAP	PPC	IMR	PAP	PPC	IMR
Andhra Pradesh	64	35	74	61	31	41
Assam	80	52	78	86	57	48
Bihar	36	18	74	41	22	56
Gujarat	46	27	68	36	21	47
Haryana	61	34	70	63	24	63
Karnataka	45	24	66	40	22	34
Kerala	118	60	15	88	43	15
Madhya Pradesh	41	26	103	38	22	61

Uttar Pradesh	61	33	89	72	41	67
West Bengal	65	38	60	65	42	45
India	55	31	79	54	30	47

Note: The data on Infant Mortality Rate (IMR) given above are in fact averages of IMRs estimated for 1995 and 1996 by the Sample Registration Scheme of the Registrar General of India.

4.2.10 Kerala is distinct from other states for its achievements in the field of health care. The indicators of health like infant mortality rate, birth rate, proportion of institutional births, life expectancy etc. show that Kerala is way ahead of the rest of the country in this respect. These indicators also reflect a moderately high level of health status in Punjab as well. Yet, *Table 4.3* shows that the level of morbidity is relatively high in these two states. The “true” morbidity prevalence in a population depends on its age distribution, since

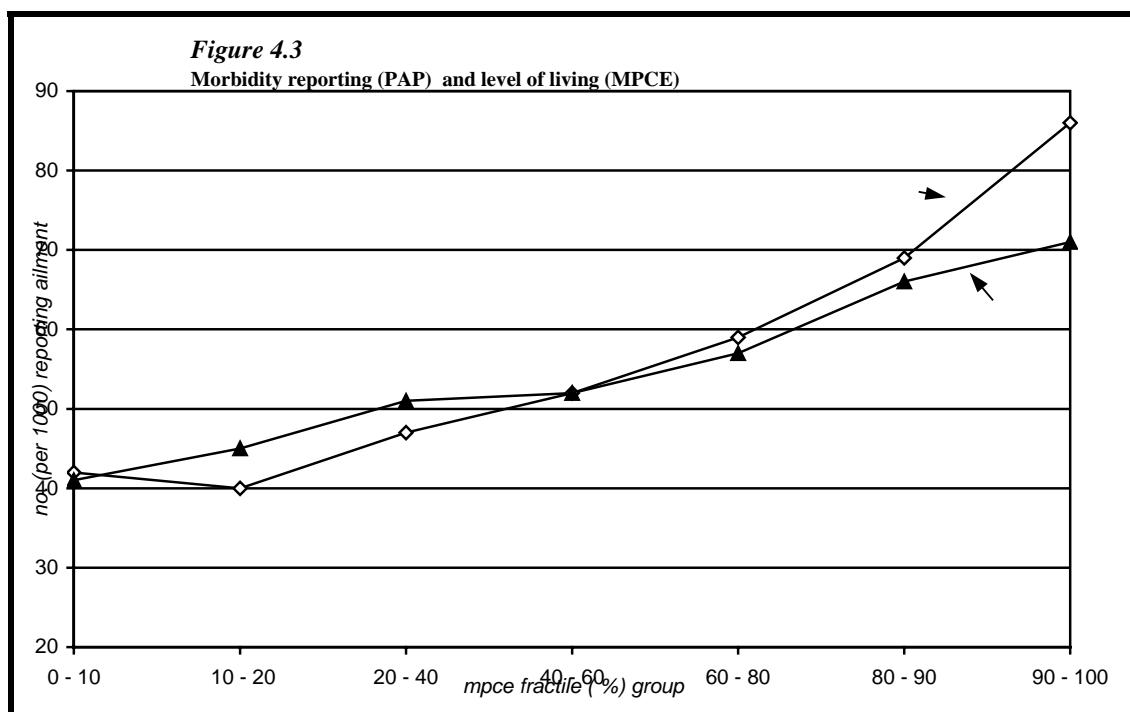

morbidity among those aged 60 years or more is observed to be much higher than the rest. With the availability of better health care, the longevity of the people is expected to rise, leading to a relatively older age-distribution. This may *inter alia* be a factor underlying the observed high levels of morbidity in Kerala. The percentage of the aged (60 years and above) in Kerala (9.4%) was found to be much higher than that in the country as a whole (5.5%) in the present survey.

4.3 Self-perceived morbidity data

4.3.1 Self- and proxy-reporting: Morbidity data collected in the survey are based on the respondents' own assessment of their medical status, rather than on medical examination. The field staff was instructed to interview personally, as far as possible, all the adult members of a household. They were permitted to interview the female members through intermediaries in some cases. For the children, particularly the young, the field staff were required to collect the information from their mothers. But in a large-scale survey like the present one, it is practically infeasible to contact and interview each member personally. The estimates of the Pilot Survey on Morbidity conducted in the NSS 17th round (1961-62) shows that a little over a third of the data was collected through self-reporting. For the 17th round survey, the instruction to the field staff, in this respect, was similar to that of the present survey. Thus, a large part of the data of the present round too, it is felt, were obtained from proxy-respondents.

Table 4.4 gives separate estimates of proportion (per 1000) of ailing persons based on proxy- and self-reported data of the 17th round. The table shows that proxy-reporting tends to underestimate the level of morbidity. In the rest of the discussion, the method of collecting morbidity data through interviews, of both self- and proxy-respondents, is referred to as "self-perceived morbidity reporting" or just "morbidity reporting".

4.3.2 Health consciousness and morbidity reporting: There is a well established direct association between morbidity reporting and level of health consciousness. In an attempt to understand how health consciousness influences morbidity reporting, Infant Mortality Rates (IMRs) estimated through the Sample Registration Scheme of the Office of the Registrar General of India are also provided alongside PAPs and PPCs in *Table 4.3*. IMR is a widely accepted indicator of general health of a population and health care services available to them. Moreover, the better the health care services

the higher is the level of health consciousness expected to be. Thus, IMR has been taken as a broad indicator of health consciousness. Interestingly, while IMRs and PAPs for rural areas of Kerala, Punjab and Madhya Pradesh suggest a negative relationship between infant mortality and morbidity reporting, the data on rural areas of Bihar, Assam, Rajasthan, Orissa and Uttar Pradesh seem to point to the contrary. The table also reveals similar features for urban PAP as well as PPC of rural and urban areas.

4.4.3 Morbidity reporting and level of living: *Figure 4.2* shows the relationship between morbidity reporting and level of living, as measured by per capita monthly consumption expenditure (MPCE). The data on household consumption expenditure were collected through a much smaller set of questions than the elaborate schedule of enquiry generally used in NSSO for collecting consumption data. These were used for working out average MPCE during decile and quintile groups, which are, in general, referred to as 'fractile groups' in this report. *Figure 4.3* presents the estimated PAP for each fractile group separately for rural and urban areas.

4.3.4 *Figure 4.3* clearly reveals a positive association between MPCE and PAP, in both rural and urban areas. The range of variation in PAP was larger in rural areas than in urban areas. If MPCE is considered to be a proxy for level of living of the households, the data appear to show that the level of living. This may mean either that the poor are less prone to sickness than the rich, or that reporting of morbidity improves with improvement in the level of living. Of the two hypotheses, the second seems to be the more plausible.

4.3.5 Recall lapse: The point prevalence of morbidity (PPM), given in *Table 4.5*, is

the previous year for each household, and the deciles and quintiles of MPCE were

Table 4.4

Number (per 1000) of persons reporting ailment (PAP) during the 15 days through proxy- and self-reporting in NSS 17th round (Sept. '61 - July '62)

gender	India			
	PAP by type of reporting			p.c. of self-reporting
	self	proxy	all

estimated for each state / u.t. separately for rural and urban areas. The population was accordingly classified into different from the point prevalence rate as recommended by the Expert Commission on Health Statistics of the W.H.O., which measures the frequency of spells of ailments in existence at a particular point of time. The estimates given in the table, on the other hand, represent the number of persons (per

Table 4.5

Point prevalence of morbidity (PPM) on the 15th day preceding and the day before the date of survey

reference day	India		
	male	female	person
Rural			
preceding 15th day	23	25	24
day before	28	30	29
Urban			
preceding 15th day	21	26	23
day before	27	30	29

Note: PPM is measured as the number of persons (per 1000) reporting any ailment on the reference day.

1000) reported to be sick on the reference day. The table gives estimates based on two different reference days, viz. the day before and the 15th day before the date of survey. These two sets of estimates are based on two different modules of questions in the schedule of enquiry. The estimates relating to the day before the date of survey are based on the data collected through a direct one-shot question regarding the morbidity status of an individual. On the other hand, the estimates relating to morbidity status of the individual as it existed 15 days ago are derived from the data on duration of the ailments reported for the reference period of 15 days preceding the date of survey. These two sets of estimates are used here to

examine the extent to which the morbidity data of the present survey are affected by recall lapse.

4.3.6 The table shows that the PPM for the day before is higher than that for the 15th day before the date of survey for male and female populations of both rural and urban areas. The PPM for the 15th day before is generally lower than that for the day before by about 20%. This corroborates the observation, made in the "Pilot Enquiry on Morbidity" conducted in the 17th round of NSS, that morbidity information based on recall period longer than a week tends to underestimate the level of illness.

Table 4.6

Number (per 1000) of ailing persons (PAP) and prevalence rate (PR) of ailment from different rounds of NSS

gender	1995-96 52nd round			1986-87 42nd rd.	1973-74 28th rd.	India 1961-62 17th rd.
	PAP (estimated) (15 days)	derived PAP (30 days)	derived PR (15 days)	PAP (30 days)	PR (15 days)	PAP (30 days)
	(1)	(2)	(3)	(4)	(5)	(6)

Persons	54	84	55	31	42	131

Note: 1. The recall periods used in different rounds are shown in the column headings in parentheses.

2. The figures in column 3 are the PAPs for a 30-day recall period, derived from the estimated PAPs and PPCs of any ailment based on 15-day recall period data.

4.4 Prevalence rates in the past and in the present

4.4.1 Morbidity rates from different NSS rounds: *Table 4.6* gives the morbidity rates estimated by the NSS for the country as a whole since 1961-62. The morbidity enquiries conducted earlier, in the 7th to 13th rounds, were exploratory in nature. In these rounds, the definition of sickness adopted was rather stringent and did not include the chronic non-disabling cases as also the residual effects of an ailment. The estimates of these rounds are, therefore, not comparable with those of the latter rounds.

4.4.2 The morbidity rates estimated from the four NSS rounds, presented in the table, are not based on same duration of reference period. The estimated PAPs of the present round (*in column 2*) and the 28th round are based on a reference period of 15 days preceding the date of survey, while those of the 17th and 42nd rounds are based on a 30-day reference period. Further, estimates of proportion (per 1000) of ailing persons (PAP) are not available from the 28th round; it gives only the prevalence rates (PR). For making comparison over time possible, therefore, PRs (with 15-day recall period) are derived for the present round from the estimated population and estimated number spells reported by the entire population. For comparing the estimates of the present round with those of the 17th and 42nd rounds, PAPs for a 30-day reference period were estimated as follows:

$$\text{PAP (30-day recall period)} = \text{PAP (15-day recall period)} + \text{PPC (15-day recall period)}$$

The PAPs for a 30-day recall period, thus derived from the estimates of the current round, are presented in *column 3* of *Table 4.6*. Clearly, the derivation involves some approximation as it is based on two rather

Table 4.7

Source for 28th round estimates: Sarvekshana, Vol. iv, Nos. 1 & 2, July-Oct. 1980, pp. 20 & 21.

* represents that data on the specific disease was not collected separately in the survey.

unrealistic assumptions. First, no person reverts to a state of illness within a month of recovering from one. Second, a person is afflicted with one ailment at a time. For the first, though there is no data relating to time elapsed between two consecutive states of illness, it can be said that the proportion of such cases is not likely to be too high to vitiate the comparison attempted below. The second assumption is relatively safe and is not expected to affect the comparison seriously, since the number of spells of ailment per ailing person is reported to be only 1.02 and 1.01 in the present round for rural and urban areas, respectively.

4.4.3 *Table 4.6* shows that the urban morbidity rates from the present round are higher than the comparable estimates of the 28th and 42nd rounds. But the highest morbidity rates were reported in the pilot

survey of the 17th round (1961-62) conducted to explore various procedures for improving the reporting of self-perceived morbidity. Further, the table does not reflect any notable rural-urban differential, except in the 42nd round. The urban estimates of PAP are found to be inexplicably low in the 42nd round. The observed differences in the estimates can not be taken as reflection of actual changes over time, because they also reflect the effects of adopting different methodologies for the surveys. For instance, while a short schedule, exclusively meant for collecting morbidity data, was used for the Pilot Survey of the 17th round, a much longer schedule covering other topics like maternity and child care, problems of the aged, etc. was used for the present round.

4.4.4 Changes in disease-specific morbidity rates: Disease-specific morbidity rates based on self-perceived morbidity data are seldom reliable. The early attempts made in the 7th, 11th, 12th and 13th rounds of NSS were met with little success. A very high proportion of ailments fell in the heterogeneous groups like 'other diagnosed fevers', 'other undiagnosed fevers', 'stomach troubles' and 'other diagnosed diseases'. A similar feature is also observed in the estimates of the 28th round as well as the present round. In fact, it is much more difficult to collect reliable information on the cause of illness than on just the illness status without medical examination. Excepting the sicknesses with clearly marked symptoms like measles, epilepsy, etc. information on cause of illness is mostly very difficult to obtain. In some cases, however, the patient comes to know

about the cause from the practitioner treating the ailment. Even then, a large proportion of cases are likely to be misclassified. Notwithstanding the doubtful quality of disease-specific data, an attempt is made here to compare the estimates of morbidity rates of the 28th round and the present round for some selected diseases which are known to occur with marked symptoms or are easily diagnosed.

4.4.5 *Table 4.7* gives some selected disease-specific morbidity rates of the 28th round (1973-74) and the 52nd round (1995-96) separately for rural and urban areas. It is seen that the prevalence rates of the chronic diseases included in the table have declined in both rural and urban areas, except that prevalence of epilepsy in urban areas seem to have risen during this period. Incidence of measles seems to have fallen in rural areas, but there was no perceptible change in urban areas. Information on Diarrhoea, Dysentery and Cholera was collected separately in the 28th round, while no distinction was made between these three causes in the present round. As a result, the incidence rate of Diarrhoea & Dysentery (including Cholera) estimated in the present round is found to be much higher than the estimates for the three causes taken together in the 28th round estimates. Possibly, a number of cases, which could not be ascertained to be Diarrhoea or dysentery, were recorded as 'other diseases' in the 28th round to avoid misreporting. Injury due to accident is a major cause of morbidity. The estimates suggest a substantial rise in accidents, particularly in urban areas.

4.5 Treatment of ailments

4.5.1 Proportion of ailing persons treated: *Table 4.8* gives the percentage of ailing persons treated during the reference period estimated from the 42nd round (1986-87)

and the present round (1995-96). In both the surveys, percentage of ailing persons treated is found to be higher in urban areas than in rural areas. The reported rates of treatment of the sick do not indicate any perceptible gender bias in either of the surveys. Moreover, the results of the two rounds do not reveal any detectable change over time in the percentage of ailing persons treated.

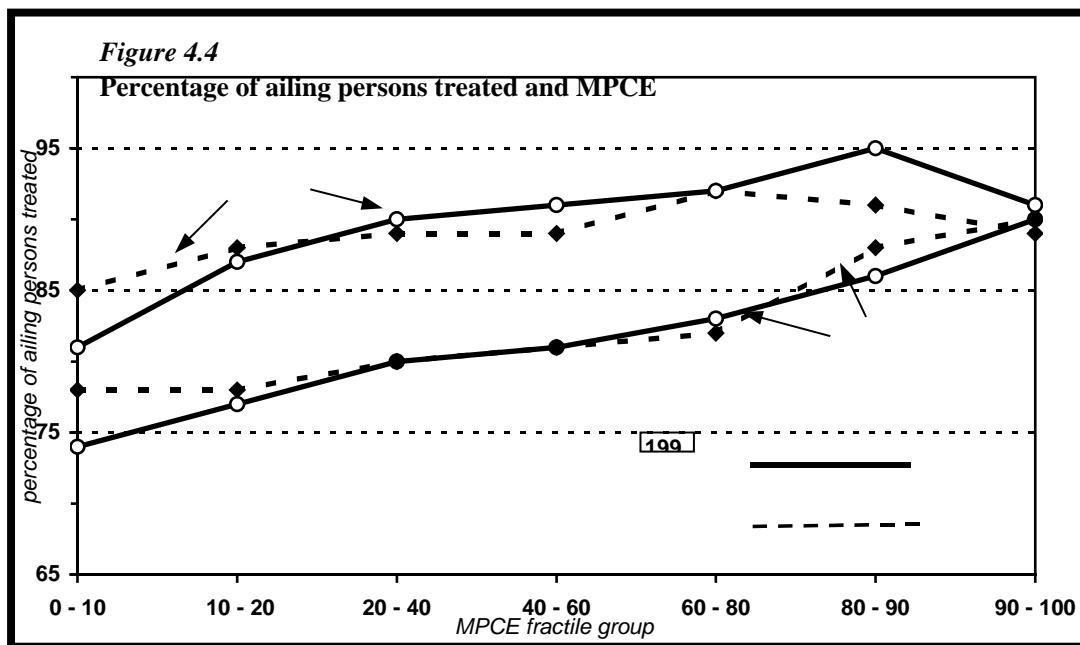

4.5.2 Ailing persons treated and MPCE: *Figure 4.3* reveals the relationship between the percentage of ailing persons treated and monthly per capita consumption expenditure (MPCE) separately for rural and urban areas. It also shows the nature of change in the relationship during the decade preceding 1995-96, as revealed by the estimates of the 42nd round and the present round. It must be noted that the MPCE data of the 42nd round (1986-87) were based on responses to a single question on the average monthly household consumption expenditure (MHCE) during the previous year, while the average MPCE data of the present round are based on a more detailed set of questions.

Being based on a single question, the responses relating to consumption expenditure, in the 42nd round, were bunched on multiples of 100 or 50. Thus, the MPCE, derived from MHCE and household size in the 42nd round, was not discriminating enough to be a good proxy for the level of living of the households. The underlying cause for the flatter pattern of the relationship in the 42nd round, as observed from the figure, appears to be the relatively less discriminating nature of the MPCE data.

Table 4.8

Source of 42nd round estimates:
NSS report no. 364.

"financial problem" was next in importance as a reason for no treatment, accounting for 24% and 21% of the untreated ailments in

4.5.3 Untreated ailing persons in 1995-96:

The percentage of untreated ailing persons (seen from *Figure 4.3*, as the distance of the plotted points from the line representing 100%) varied from about 26% in the lowest expenditure group to 10% in the top expenditure group in rural areas. In urban areas, the variation in the percentage was less pronounced -- about 9% to 19%. It may be mentioned here that the untreated illnesses included self-medication and home remedies as well as no care.

4.5.4 Reasons for no treatment: The reasons associated with no treatment were also collected in the survey in form of codes. *Table 4.9* gives the percentage distribution of untreated ailments by reason for no treatment, as estimated from the 42nd round and the present round. It is seen that, in 1995-96, the reason most often cited for no treatment was that the ailment was "not serious". This reason was reported for over 50% and 60% of the untreated ailments in rural and urban areas, respectively. The

Table 4.9

Percentage distribution of untreated ailments by reason for no treatment from NSS 42nd and 52nd rounds

reason for no treatment	India

others	10	5	12	6
all	100	100	100	100

Note that the estimates for 'others' of the 52nd round include the cases where reasons are not reported.

Source of 42nd round estimates: NSS report no. 364.

rural and urban areas, respectively.

4.5.5 Changes in reason for no treatment: A comparison between the estimates of the

42nd round and the present round reveals a marked shift in the reasons for not treating an ailment, though the relative importance of the reasons for no treatment does not seem to have been different during the two survey periods. The pre-coded reasons used for data collection in the 42nd round (1986-87) were same as those of the present round. It is seen that the share of the reason "ailment not serious" in the untreated ailments declined from 75% to 60% in rural areas and 81% to 52% in urban areas. On the other hand, financial reasons were cited more often in 1995-96 than in 1986-87 in both rural and urban areas. With the proportion of untreated ailments remaining more or less unchanged, it can be said that, as compared to 1986-87, a larger proportion of ailments in 1995-96 were not treated because the cost of treatment was higher than the households could afford.

4.5.6 Sources of non-hospitalised treatment: *Table 4.10* gives the percentage distribution of non-hospitalised treatments by source of treatment for 1986-87 and 1995-96. The estimates are based on the data on actual utilisation of health services while undergoing a spell of ailment during the reference period. It is seen that private doctors were the most important single source of non-hospitalised treatment during both the survey periods. They accounted for 55% of the treatments in rural as well as urban areas of the country as a whole in 1995-96. In fact, the private sector consisting of private doctors, nursing homes, private hospitals, charitable institutions, etc., accounted for over four-fifths of medical treatments in the country. Moreover, a comparison with the corresponding estimates of the 42nd round reveals a discernible rise in the share of private sector in non-hospitalised treatment of ailments over time.

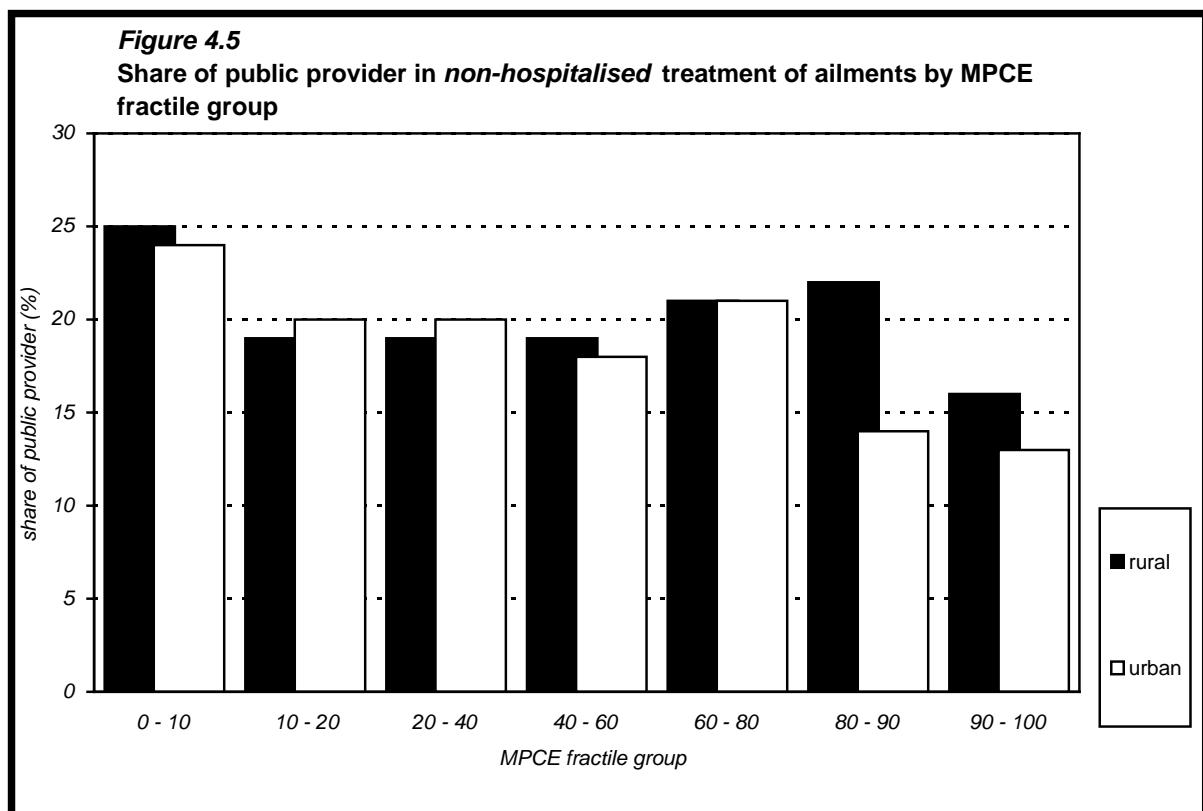

4.5.7 Share of public provider in treatment of illnesses: The public providers for health care include government hospitals, clinics, dispensaries, Primary Health Centres (PHCs) and the Community Health Centres (CHCs), and the state and central government assisted ESI hospitals and dispensaries. The rest of the providers fall in the category "private" sources. *Figure 4.4* shows how the share of public provider in treatment of ailments varies with the expenditure class. It reveals largely a declining trend in the reliance on the public sector for non-hospitalised treatment with rise in MPCE in urban areas of the country. The pattern for rural areas, however, does not exhibit clear relationship, except that the share of public provider in non-hospitalised treatment was the highest (25%) in the bottom decile and the lowest (16%) in the top decile.

Table 4.10

Total	100	100	100	100

Note: The estimates of the 52nd round are based only on the treatments with reported source of treatment.

Source of 42nd round estimates: NSS report no. 364.

4.5.8 Share of public provider in non-hospitalised treatment: Table 4.11 gives the percentage of ailments treated by public and private providers separately for rural and urban areas of 15 major states. The table also provides the per capita public expenditure on health, as reported by the Directorate of Health Services, Ministry of Health and Family Welfare. The figures given in columns 2 & 5 of the table are, in fact, the estimates of percentage of ailments treated from government sources, whether or not any treatment was received from non-government agencies for the same ailment. Therefore, columns 3 & 6 of the table give percentage of ailments exclusively treated from non-government sources. It is seen that in rural and urban areas of all the major states, except for rural Assam and rural Orissa, the private sector is the main

provider of non-hospitalised treatment of illnesses. The percentage of ailments treated from any source was about 83 and 92 in rural and urban areas of the country, respectively. In rural areas, 19% of the ailments were treated by government sources and the rest of the treated ailments (64%) were treated exclusively from non-government sources. Similarly, in urban areas, 20% of the ailments were treated from government sources and 72% of the were treated exclusively from non-government sources.

4.5.9 Inter-state variation in ailments treated by government sources: The table reveals a wide inter-state variation in percentage of treated ailments as well as in percentage of ailments treated from government sources. Relatively high percentage of treated ailments were reported

Table 4.11

Percentage of ailments receiving non-hospitalised treatment by public and private providers and per capita public expenditure on health in 15 major states

Uttar Pradesh	8	83	91	9	85	94	43
West Bengal	15	65	80	19	72	91	55
India	19	64	83	20	72	92	70

Note: 1. The estimates of the 52nd round are based only on the treatments with reported source of treatment.

2. The data on per capita public expenditure on health (PCPHE) relate to 1989-90 and are taken from 'Health Information of India' (1993), Central Bureau of Health Intelligence, Directorate General of Health Services, Ministry of Family Welfare, Government of India.

in rural and urban areas of Punjab, Haryana and Gujarat, and rural areas of Uttar Pradesh and Rajasthan. But, even among these states, the utilisation of government sources for treatment of ailments varied considerably. While utilisation of public health care facilities for treatment of ailment was found to be among the lowest four in Punjab, Haryana and rural Uttar Pradesh, it was reported to be the highest in rural Orissa and Rajasthan. In Gujarat, the percentage of ailments treated from government sources was moderately high. Interestingly enough,

while the utilisation of public sector for medical treatment was reported to be least in Punjab and Haryana, the highest two per capita public expenditure on health (PCPHE), as per the figures compiled by the Directorate of Health Services for 1989-90, were reported in these two states. The PCPHE was relatively high in Rajasthan and Gujarat as well. In fact, among the five states reporting high percentage of treated ailments, the PCPHE was relatively low in only Uttar Pradesh.

4.5.10 At the other extreme, the lowest two percentages of treated ailments were reported in rural areas of Assam and Orissa. However, in both these states, the public sector constituted the main provider of curative health care, though Orissa was among the states with four lowest PCPHE and Assam with a relatively low PCPHE.

4.5.11 Changing role of public provider in treatment of ailments in major states: Table 4.12 gives the percentage of ailments receiving any non-hospitalised treatment from government sources during the reference period for 15 major states. The table gives estimates of the 42nd round (1986-87) as well as those of the present round (1995-96). It is seen that, for the country as a whole, the percentage of ailments receiving non-hospitalised treatment from government sources declined from 21% to 19% in rural areas and 24% to 21% in the urban areas during 1986-87 to 1995-96. The declining reliance on government sources for non-hospitalised treatment of ailments is observed for rural and urban areas of all the major states, except rural and urban areas of Andhra Pradesh, urban Bihar and urban Maharashtra. The sharpest decline was recorded for Assam and Rajasthan -- the two states among the three reporting highest shares of public providers in non-hospitalised treatment. Orissa, the other state with a relatively high share of public providers in non-hospitalised treatment,

registered no decline in the percentage of ailments treated from government sources in the rural areas, but registered a sharp fall in the percentage in its urban areas.

Table 4.12

Note: 1. The estimates of the 52nd round are based only on the treatments with reported source of treatment.

2. * denotes estimate not available.

4.6 Hospitalised treatment of ailments

4.6.1 Proportion of persons hospitalised per annum: Medical treatment of an ailing person as an in-patient in any medical institution having provision of treating the sick as in-patients is considered as hospitalised treatment. *Table 4.13* gives the estimated of number (per 1000) of persons hospitalised during a reference period of 365 days. It is seen that the estimated proportion of hospitalised persons differed substantially between rural and urban areas. During 1995-96, about 2 per cent of the urban population were hospitalised any time during a reference period of 365 days. The proportion of persons hospitalised in the rural areas was much lower (1.3%). The survey results, however, do not reflect any perceptible gender-differential in this respect, either in rural or urban areas.

4.6.2 The table also provides the available estimates of the 42nd round (1986-87). The report of the 42nd round survey do not give the gender-specific estimates on the rate of hospitalisation. Comparison between the estimates of the two rounds shows that, in rural areas, the rate has substantially declined during the period, while in urban areas it seemed to have increased marginally.

4.6.3 Hospitalised treatment and level of living: *Table 4.14* reveals the relationship between the number (per 1000) of persons hospitalised and average monthly per capita consumption expenditure (MPCE) during the previous year separately for male and female populations of rural and urban areas of the country as a whole. MPCE is a widely recognized proxy for level of living. The estimates suggest a strong positive association between MPCE and the rate of hospitalisation both in rural and urban areas. The rise in the rate is steeper for rural than urban areas. For the rural population, the

Table 4.13

Number (per 1000) of persons hospitalised in 1995-96 and 1986-87

gender	India	
	1995-96 (52nd rd.)	1986-87 (42nd rd.)

Source of 42nd round estimates: NSS report no. 364.

rate rises steadily from 4 in the lowest decile to 37 in the top decile. For the urban population, the rate rises from 12 to 38 with the MPCE fractile group. It may be noted here that the expenses associated with hospitalisation of a member are reflected in the average MPCE of the household. As a result, a household with a member receiving hospitalised treatment any time during the 365 days preceding the date of survey is likely to be classified in a higher fractile

Table 4.14

Number (per 1000) of persons hospitalised during last 365 days by MPCE fractile group

gender	India							
	mpce fractile group							
	0 - 10	10 - 20	20 - 40	40 - 60	60 - 80	80 - 90	90 - 100	all
Rural								
male	3	6	8	10	16	22	39	14
female	4	5	8	9	15	21	34	13
person	4	6	8	10	15	21	37	13
Urban								
male	12	13	17	19	20	26	39	20
female	13	13	15	20	22	28	36	20
person	12	13	16	19	21	27	38	20

group than the one to which the household should otherwise belong. This factor is certain to exaggerate the extent of positive association between level of living and rate of hospitalisation, if any exists, and may create an apparent positive association even when there is none.

4.6.4 Gender bias in hospitalised treatment: The survey results, given in *Table 4.14*, do not indicate presence of any gender bias within a MPCE fractile group, except in the top deciles of the rural and urban populations. In this fractile group too, the rate for the male population was only marginally higher than that for the female population.

4.6.5 Proportion of persons hospitalised -- inter-state variation: *Table 4.15* gives the estimated proportion (per 1000) of persons hospitalised during a reference period of 365 days in rural and urban areas of 15 major states. Estimates reveal a wide inter-state variation in the proportion. In Kerala, the proportion, for both rural and urban areas, was much higher than in the rest of the major states. The estimates for the country as a whole were 13 and 20 for rural and urban areas, respectively, while the corresponding estimates in Kerala were 70 and 65. The three other states reporting relatively high proportions of persons hospitalised, viz. Haryana, Maharashtra and Tamil Nadu, were way behind Kerala, with the proportion ranging between 18 to 26. These are quite consistent with the information available from the official source of the Directorate of Health Services, Government of India.

4.6.6 The data on health care services available from the official sources is regularly compiled by the Directorate of Health Services, Ministry of Health and Family Welfare of Government of India. The information relating to availability of beds for hospitalised treatment, according to

the Directorate, is also included in *Table 4.15*. The survey results on hospitalisation seem to be fairly consistent with the data available from the official source. Kerala with an exceptionally advanced health care system in the country had a hospital bed for every 382 persons according to the official source, and the results of the present survey indicate an exceptionally high proportion of persons receiving hospitalised treatment in the state. Among the other states reporting high proportion of persons receiving hospitalised treatment, Maharashtra and Tamil Nadu had a hospital bed, on an average, for a relatively small number of persons. However, in Haryana, which

Table 4.15
Proportion (per 1000) of persons hospitalised in rural and urban areas and population per bed in the state

state	no. (per 1000) hospitalised		population per hospi- tal bed
	rural	urban	
Andhra Pradesh	14	17	2536

Tamil Nadu	18	23	1120
Uttar Pradesh	8	14	2593
West Bengal	11	22	1271
India	13	20	1412

Note: The data on population per bed relate to 1.1.1993, except for Assam(1991), Bihar(1992), Tamil Nadu(1990) and Uttar Pradesh(1986) and are taken from 'Health Information of India' (1993), Central Bureau of Health Intelligence, Directorate General of Health Services, Ministry of Health and Family Welfare, Govt. of India.

reported a high proportion of persons reporting hospitalised treatment, the ratio of population to number of hospital beds was much higher than the national average. Again, for Gujarat, which had a low population to hospital beds ratio (714), the proportion of hospitalised persons was not noticeably higher than the national average.

4.6.7 Shares of different types of hospitals in hospitalised treatment: *Table 4.16* gives the share of different types of hospitals in hospitalised treatment of the rural and urban population of the country. Like the non-hospitalised treatment of ailments, the private sector was the main provider of hospital-based health care both in rural and urban areas. It is seen that, in 1995-96, about 56% and 57% of the hospitalised treatments, in rural and urban areas, respectively, were taken from non-government sources. The private hospitals and the public hospitals were the two most important single sources of hospital-based treatment of ailments. Each accounted for a little over 40% of hospitalised treatments of both rural and urban population. Nursing homes, the other important constituent of the private health care sector, treated 8% and 11% of hospitalisation of rural and urban population, respectively. Charitable institutions played an important minor role in providing hospitalised treatment to both rural and urban population. For the rural population, however, the PHCs and CHCs accounted for a higher proportion of hospitalised treatment than the charitable institutions.

4.6.8 Changing share of public providers in hospitalised treatment: *Table 4.16* also gives the per 1000 distribution of

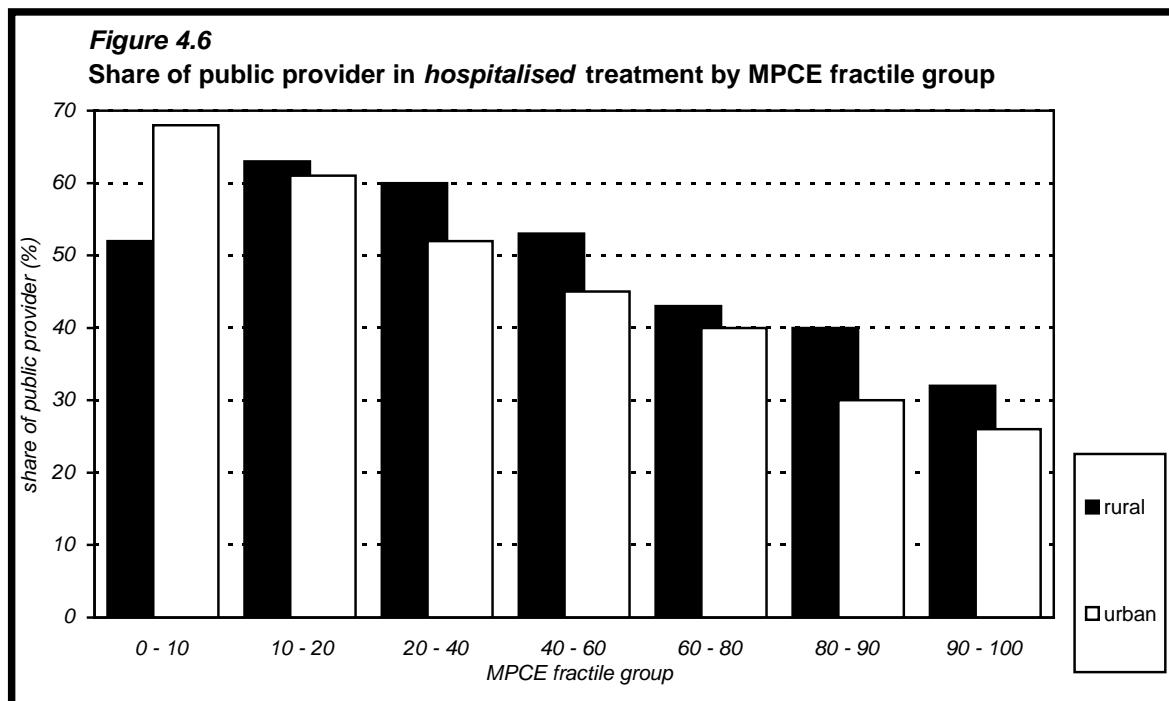

Table 4.16

Per 1000 distribution of hospitalised treatments by type of hospital during 1986-87 and 1995-96

type of hospital	Rural		Urban	
	1995-96 (52nd)	1986-87 (42nd)	1995-96 (52nd)	1986-87 (42nd)

Source of 42nd round estimates: NSS report no. 364.

hospitalised treatments by type of hospital estimated from the 42nd round (1986-87). The public providers for hospital-based health care include government hospitals, Primary Health Centres (PHCs) and the Community Health Centres (CHCs) with the provision for treating the sick as in-patients, and the State and Central government assisted ESI hospitals and dispensaries. The table shows a sharp decline -- from about 60% in 1986-87 to about 43% in 1995-96 -- in the share of public provider in hospitalised treatment of both rural and urban population. The sharpest decline is observed in the reliance on public hospitals, while private hospitals and nursing homes have substantially improved their shares during the period. The importance of PHCs and CHCs for the rural population appears to have remain unchanged.

4.6.9 Treatment in public sector hospitals and MPCE: Figure 4.6 presents the percentage of hospital-based treatments received from government establishments by MPCE fractile group for rural and urban areas of the country as a whole. The percentage share of the public sector in hospitalised treatment in different fractile groups varied over a very wide range -- from 32% to 63% in rural areas and form 26% to 68% in urban areas. The figure reflects a steady decline in the reliance on public provider for hospitalised treatment with a rise in MPCE. The only departure from this pattern is noted for the rural population in the lowest decile, which reported lower dependence on public providers than the decile immediately above it. On the whole, the poorer households appear to rely more on the public sector for hospitalised treatment than the better-off sections of the population, both in rural and urban areas.

4.6.10 Share of public provider in hospitalised treatment -- inter-state variation: Table 4.14 gives the proportion (per 1000) of hospitalised treatments received from public sector hospitals by rural and urban population of 15 major states. In most of the states, the proportion for rural and urban population differed little. On the whole, the rural population seems to rely more on the public sector than the urban population. However, in Andhra Pradesh, Gujarat, Haryana, Madhya Pradesh and Rajasthan, the proportion was seen to be considerable higher for the urban population than the rural population.

4.6.11 The table indicates that the reliance on the public sector for hospitalised treatment varies a great deal from state to state. The proportion (per 1000) of hospitalised treatments received from public sector hospitals varied form 225 in rural

Andhra Pradesh to 906 in rural Orissa. Apart from Orissa, three other states, viz. West Bengal, Assam and Rajasthan, reported relatively high shares of public sector in hospitalised treatment of both rural and urban population. This is quite consistent with the information on public and private sector hospitals available from the official source of the Directorate of Health Services, Government of India.

4.6.12 The information on number of beds in public and private hospitals in different states is available from the Directorate of Health Services, Ministry of Health and Family Welfare of Government of India. The percentage of beds in public sector hospitals, derived from the information available from the Directorate, is also included in *Table 4.17*. The survey results on utilisation of public sector hospitals in different states are seen to be broadly consistent with the data available from the official source. However, according to the Directorate, there were only public sector hospital beds in Madhya Pradesh and Rajasthan on 1.1.1993, but the results of the present survey reveal that a sizable part of the hospitalised treatment in these two states was provided by the private sector hospitals. Notwithstanding this discrepancy, it is seen that, in the present survey, the highest 5 shares of public sector in hospitalised treatment were reported in the states which have the 5 highest proportion of public sector hospital beds, according to the Directorate.

4.7 Cost of non-hospitalised treatment

4.7.1 In the present survey, data on expenses incurred for medical treatment were collected for every spell of ailment, separately for hospitalised and non-hospitalised treatment. For the non-hospitalised treatments, information on

Table 4.17

Number (per 1000) of hospitalised treatments received from public provider

state	treated in govt. hospital		percentage of beds in government hospitals
	rural	urban	
Andhra Pradesh	225	362	10

Punjab	394	276	74
Rajasthan	649	731	100
Tamil Nadu	411	357	79
Uttar Pradesh	471	398	75
West Bengal	820	721	87
India	453	431	65

Notes: 1. The 'not reported' cases of source of treatment are excluded.

2. The data on percentage of beds in government hospitals relate to 1.1.1993, except for Assam(1991), Bihar(1992), Tamil Nadu(1990) and Uttar Pradesh(1986) and are taken from 'Health Information of India' (1993), Central Bureau of Health Intelligence, Directorate General of Health Services, Ministry of Family Welfare, Govt. of India.

expenses was collected separately for each different treatment undergone for an ailment. The expenses other than those for actual medical treatment of a spell of ailment were also recorded separately. Medical expenses include expenditure on items like medicines, bandages, plaster etc., fees paid for medical and para-medical services, charges for diagnostic tests, charges for operation and therapies, charges for ambulance, costs of oxygen and blood etc. The "other expenses" relating to treatment of an ailment constitutes all expenses other than the medical expenditure proper incurred by the household in connection with treatment of an ailing member of the household. This category of expenditure includes all transport charges (except ambulance charges) paid by the

household members in connection with the treatment, lodging charges of the patient and her or his escort(s), attendant charges paid, and personal medical appliances purchased during the reference period. The estimates of "total expenditure" were arrived at as the sum of "medical expenditure" and "other expenditure".

4.7.2 Average expenditure for non-hospitalised treatment per ailment: *Table 4.18* gives the estimates of total per-ailment expenditure incurred for non-hospitalised treatment during the reference period of 15 days. The table provides separate estimates for treatment of male and female patients of rural and urban areas for the country as a whole. It is seen that, on an average, a higher amount was spent for non-hospitalised treatment of an ailment by the urban population than the rural population. The table also indicates presence of gender bias in respect of expenses incurred per ailment, though the estimates on proportion of ailing persons treated (*given in Table 4.8*) do not reflect any perceptible difference between the male and female population of both rural and urban areas.

4.7.3 Inter-state variation in expenditure per non-hospitalised treatment: *Table 4.19* gives the average medical and other related non-medical expenditure per treated ailment during 15 days by source of treatment for rural and urban areas of 15 major states. It may be noted that while *Table 4.18* gives expenses per ailment, *Table 4.19* gives expenses per *treated* ailment. Moreover, the estimates given in the table pertain only to the non-hospitalised treatment of ailments. The expenses relating to hospitalised treatment is discussed separately in Section 8 of this chapter.

4.7.4 Variation in medical expenditure: It is seen that the average total expenditure per treated ailment was Rs.176 and Rs.194 in rural and urban areas, respectively. Of these, about

90% were spent for medical treatment and the rest for other related non-medical expenditure. The medical expenditure per treated ailment varied widely across the states. In the rural areas, it varied from Rs.89 in Tamil Nadu to Rs.203 in Uttar Pradesh, and in the urban areas

Table 4.18

gender	rural	urban	India
male	151	187	
female	137	164	
person	144	175	

from Rs.106 in Kerala to Rs.390 in Haryana. The other states reporting relatively low medical expenditure per treated ailment in rural areas were Karnataka (Rs.108), Assam (Rs.115) and Kerala (Rs.119). In urban areas, besides Kerala, relatively low expenditure per treated ailment was reported in Tamil Nadu (Rs.112), West Bengal (Rs.126) and Orissa (Rs.128). Interestingly, contrary to what is observed for most of the states as well as the country as a whole, Orissa and Punjab reported a higher medical expenditure per treated ailment for the rural population than the urban population.

4.7.5 Medical expenditure for treatment received from government and other sources: As expected, at the national level, the average medical expenditure incurred for treatment received from government sources was lower than that received from other sources in both rural and urban areas. The statewise estimates show that treatment from government sources was by far cheaper than the other sources in rural and urban areas of all the southern states as well as Gujarat and Maharashtra. Lower cost of treatment from government sources was also reported in Urban Bihar and West Bengal. But in rural and urban areas of Assam, Haryana and Uttar Pradesh and in rural Rajasthan and West Bengal, medical expenditure reported for treatment received from government sources was higher than that received from other sources.

Note: Estimates (expenditure pre *treated* ailment) presented in this table are not based on any table given in the Appendix. This table was separately generated for discussion in this chapter.

4.8 Cost of hospitalised treatment

4.8.1 For the hospitalised treatments, information on expenses was collected separately for each different event of hospitalisation during the reference period. Besides the expenses treated as medical expenses for non-hospitalised treatment, expenditure on items like bed charges, and cost of medicines and other materials and services supplied by the hospital, charges for diagnostic tests done at the hospital were included in the medical expenditure for a hospitalised treatment. The "other expenses" relating to hospitalised treatment is the same as that for non-hospitalised treatment. The estimates of "total expenditure" for hospitalised treatment were arrived at as the sum of "medical expenditure" and "other expenditure".

4.8.2 *Average expenditure for hospitalised treatment per ailment:* Table 4.20 gives the estimates of total per-hospitalisation expenditure incurred for hospitalised treatment during the reference period of 365 days. The table provides separate estimates for treatment of male and female patients of rural and urban areas for the country as a whole. It is seen that, on an average, a higher amount was spent for hospitalised treatment by the urban population than the rural population. The table also indicates presence of a distinct gender bias in respect of expenses incurred per hospitalisation, though the estimates on proportion of persons hospitalised (*given in Table 4.13*) do not reflect any perceptible gender difference in either rural or urban areas.

4.8.3 *Cost per hospitalisation by type of hospital:* Table 4.21 gives the estimates of average total expenditure incurred for an event of hospitalisation in different types of establishments for rural and urban population of the country as a whole. It is seen that the average expenditure for

Table 4.21

gender	India	
	rural	urban
male	3,778	4,185
female	2,510	3,625
person	3,202	3,921

hospital was much lower than that from a private sector hospital in both rural and urban areas. The rural population spent, on an average, Rs.2,080 for a hospitalised treatment in a public sector hospital and Rs.4,300 for that in a private sector hospital. The average total expenditure of the urban population for a hospitalised treatment in a public and private hospital were respectively Rs.2,195 and Rs.5,344. As for the individual types, it is seen that hospitalised treatment in P.H.C./C.H.C. was the least expensive in rural areas. However, as the difficult cases are generally referred to hospitals, only the less severe patients are

treated as in-patients of P.H.Cs/C.H.Cs. This may be a reason for P.H.Cs/C.H.Cs to be least expensive in rural areas.

4.8.4 Inter-state variation in cost per hospitalisation: Table 4.22 gives the average total expenditure per event of hospitalisation during 365 days by source of treatment for rural and urban population of 15 major states. Like the non-hospitalised treatment, the cost per hospitalisation in a government establishment was minimum in Tamil Nadu. In fact, it was relatively low in all the southern states, except rural Andhra

Pradesh, as well as in Gujarat, Maharashtra and West Bengal. Moreover, on an average, the public hospitals were less expensive than the private sector hospitals in rural and urban areas of all the states, except urban Haryana. The difference between average expenditure for hospitalsied treatment received from public and private hospitals is more pronounced for the urban popualtion than the rural population. The difference in costs of hospitalised treatment from public and private sector was relatively more pronounced in West Bengal, Maharashtra and urban Orissa as well as in the southern states.
